

### Platform Overview

Empirical is the only exposure management vendor that publishes a false positive rate and measures performance. Our platform trains predictive models on near-real time exploitation telemetry and your enterprise's own data (assets, applications, controls, patching cadence) to produce calibrated probabilities of exploitation that you can measure, test, and defend to your board.

## Why security teams choose Empirical

### A common language for risk decisions

The Empirical global model grounds every prioritization decision in observable evidence. When someone asks "why are we fixing this one first?" The answer is a probability backed by real world exploitation telemetry, with critical indicators explaining the logic in real time.

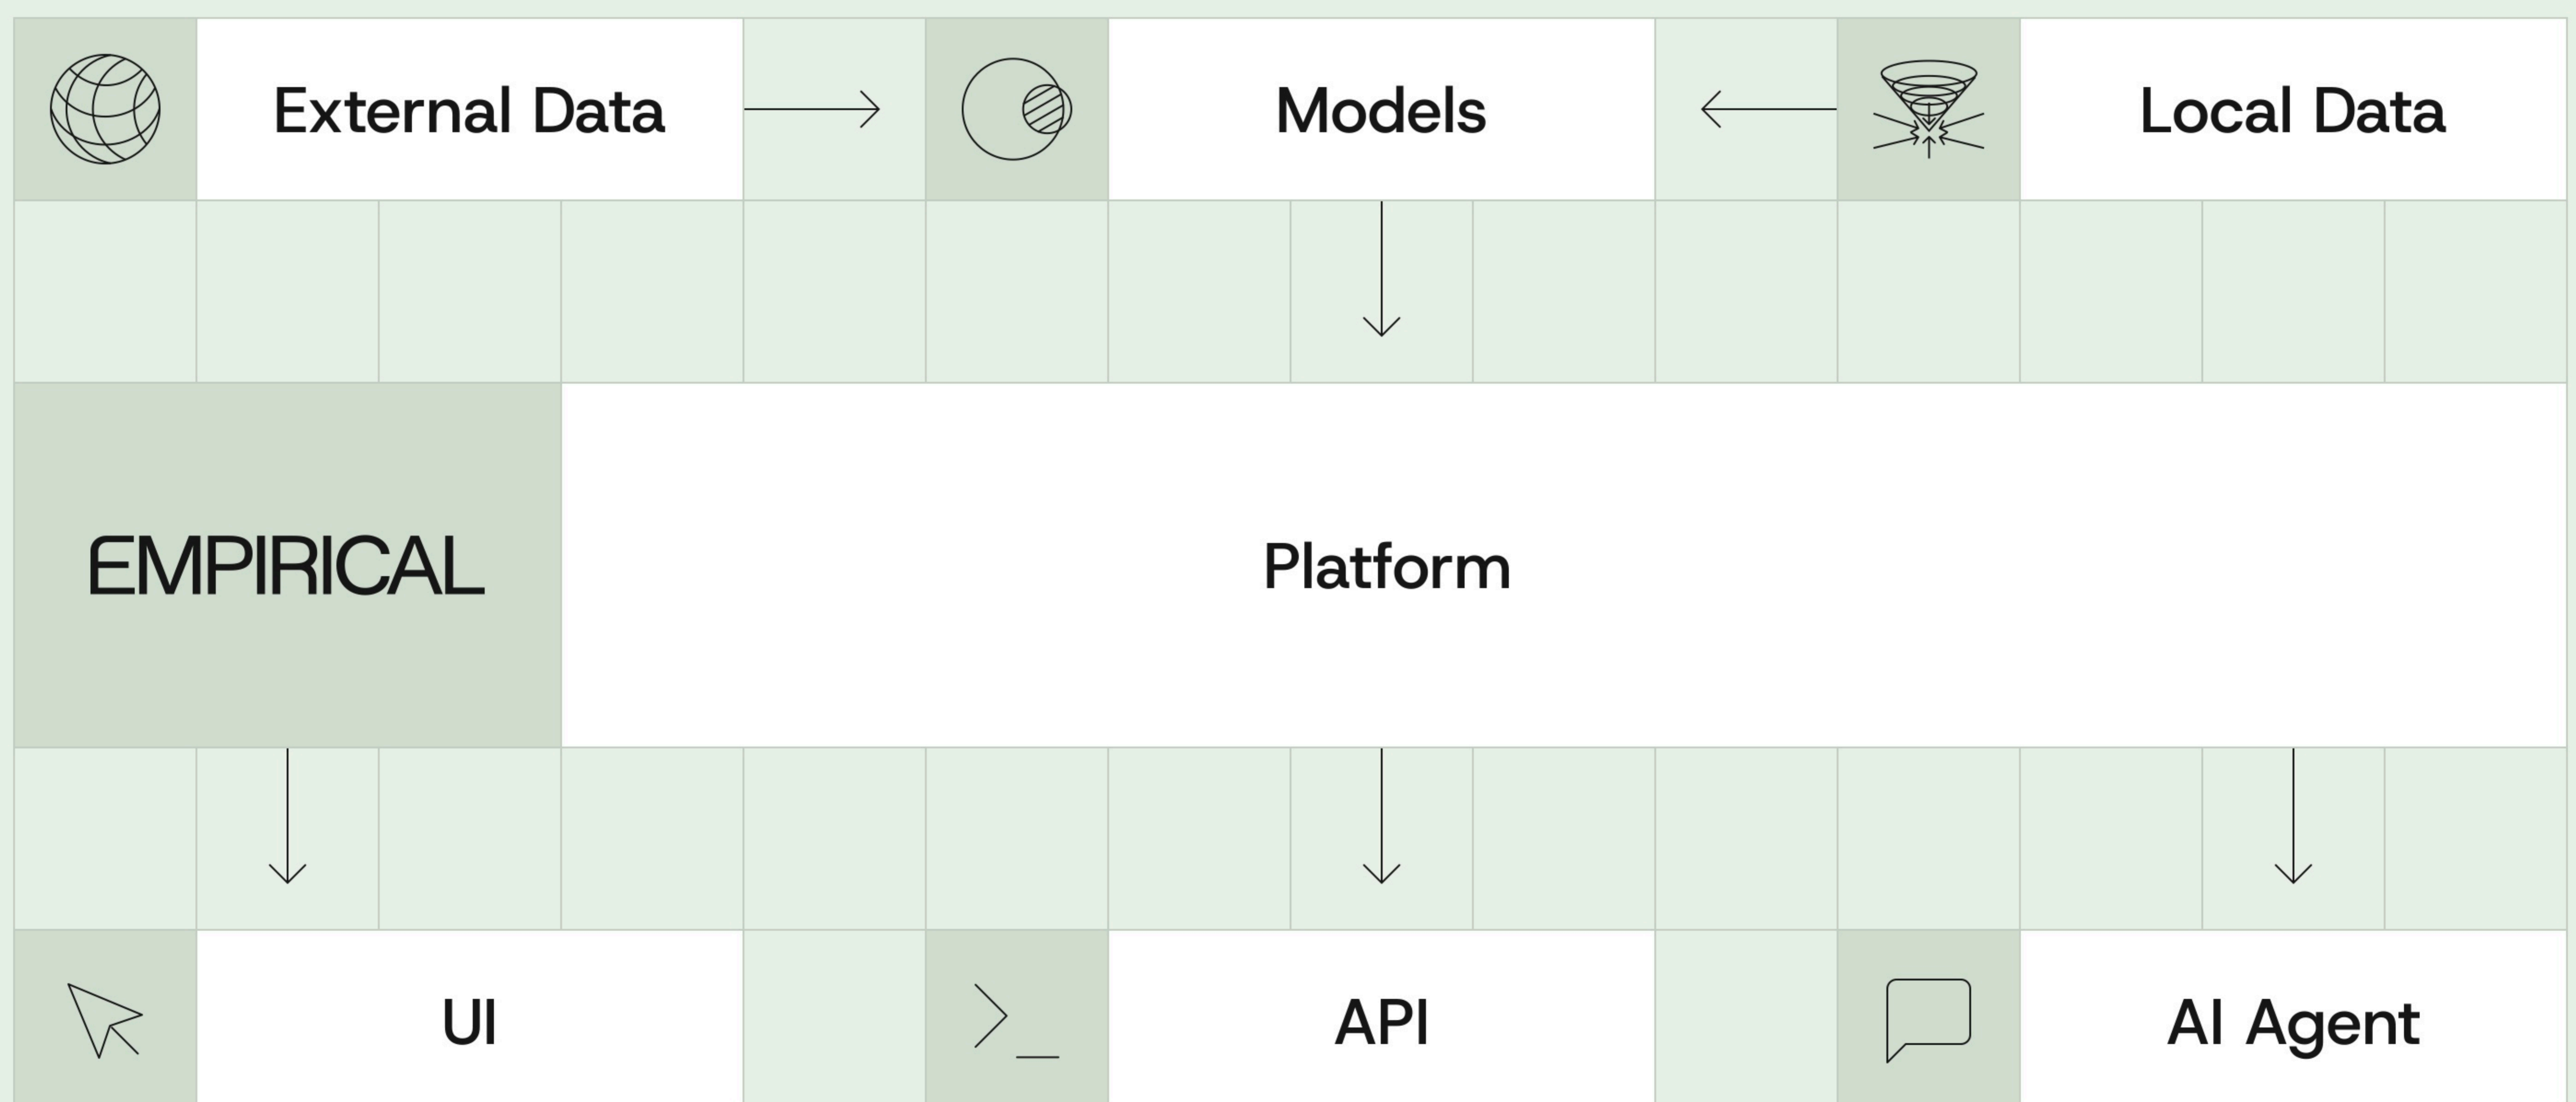

### Your context changes the answer

A critical vulnerability behind a WAF with no internet exposure is not the same risk as a medium CVE on an unpatched, public-facing server running your payments stack. Generic models can't tell the difference. Our local model can because it trains on data only your environment produces.

### We predict which vulnerabilities will be exploited in your environment.

CVSS measures severity, and EPSS predicts global exploitation probability, but neither tells you what will be exploited in your environment next month. Our models answer this crucial question. We demonstrate higher coverage and efficiency than traditional methods or off the shelf models. When fixing a limited set of vulnerabilities our predictions catch more of what actually gets exploited and waste less effort on what doesn't. We publish the data to prove our performance.

## How It Works

# EMPIRICAL

## Platform Capabilities

<h3>Switch models instantly</h3> <p>Toggle between local, global, and EPSS views. See how each model scores the same CVE and understand why they diverge.</p>	<h3>Full model transparency</h3> <p>Every data point contributing to a score is exposed. No black boxes. Inspect the features, question the output, trust the result.</p>	<h3>Validate threats with exploitation evidence</h3> <p>Cross-reference any CVE against real-time exploitation indicators: active campaigns, malware associations, exploit maturity, attacker infrastructure.</p>
<h3>AI agent for workflow automation</h3> <p>Ask our agent to triage findings, generate remediation plans, draft exception requests, or surface emerging threats grounded in the Empirical model's output, not hallucinated from irrelevant data.</p>	<h3>Connect any security tool</h3> <p>Ingest from scanners, CNAPPs, EDR, CMDB, ticketing systems, and cloud platforms. The model improves with every source you connect.</p>	<h3>17,000+ exploited-in-the-wild CVEs</h3> <p>The largest curated exploitation dataset in the industry. 12x CISA KEV. Built from the same ground-truth collection that powers EPSS.</p>
<h3>Near-real time exploitation telemetry</h3> <p>Models update with hourly exploitation signals. Not daily. Not weekly. The threat landscape moves in hours. So does the model.</p>	<h3>Forward-deployed data science team</h3> <p>Our team includes the creators of EPSS and the founders of risk-based vulnerability management. They work directly with customers to tune local models, validate results, and drive measurable risk reduction.</p>	<h3>See how your model would differ</h3> <p>Try our models with your own local data and discover their impact on your cybersecurity environment.</p>

The screenshot displays the Empirical Security web interface. At the top, there's a navigation bar with options like 'Global Model', 'Global Data', 'Your Data', 'Models', 'Insights', 'Agent', and a search bar. Below the navigation, a search query 'exploitation\_activity:0-7' is shown. A summary section provides statistics for 'Known Exploitation Activity' across various time periods: New Activity (22), 1 Week Ago (6,779), 1 Month Ago (6,520), 3 Months Ago (6,574), 1 Year Ago (6,554), and Over a Year ago (6,234). The main content area shows a table of search results for CVE-2025-24514, with columns for 'Empirical Score' (97.1% Top 1%), 'CVE ID', and 'Actions'. A detailed view for CVE-2025-24514 is shown on the right, including a 'Summary' section with a description of the vulnerability in ingress-nginx, 'Critical Indicators' (Chatter, Exploit Code, References, Vendor, etc.), 'Known Exploitation Activity' (Last Known: Mar 28, 2026), and 'Score Comparison' charts showing 97.1% for Global and 23.0% for EPSS V4.
